Radiographic procedure for forearm evaluation of Skye Terriers

One radiograph is taken of both front limbs. Identification of the images include register number of the dog, date when the radiographs were taken, marking of the limb (left, right). The dog must be adequately sedated.

Position:
Mediolateral projection of the forearm. Centre in the middle of the radius, elbow joint and carpus are visible in the image. The elbow joint is in neutral position (the angle is at least 90°). The joint space should be visible as clearly as possible. Let the carpus rotate if the forearm is crooked.

E-mail the radiographs (digital images in DICOM format) to:
